COMPREHENSIVE RADIOLOGICAL SURVEY

OFF-SITE PROPERTY N'-NORTH
NIAGARA FALLS STORAGE SITE
LEWISTON, NEW YORK

INTRODUCTION

Beginning in 1944, the Manhattan Engineer District and its successor, the Atomic Energy Commission (AEC), used portions of the Lake Ontario Ordnance Works (presently referred to as the Niagara Falls Storage Site (NFSS) and off-site properties), approximately 3 km northeast of Lewiston, New York, for storage of radioactive wastes. These wastes were primarily residues from uranium processing operations; however, they also included: contaminated rubble and scrap from decommissioning activities, biological and miscellaneous wastes from the University of Rochester, and low-level fission-product waste from contaminated-liquid evaporators at the Knolls Atomic Power Laboratory (KAPL). Receipt of radioactive waste was discontinued in 1954, and, following cleanup activities by Hooker Chemical Co., 525 hectares of the original 612-hectare site were declared surplus. This property was eventually sold by the General Services Administration to various private, commercial, and governmental agencies.¹

Modern Landfill, Inc., is the current owner of a tract from the NFSS, identified as off-site property N'-North (see Figure 1). A radiological survey of that tract, conducted September-October 1983, is the subject of this report.

SITE DESCRIPTION

Figure 2 is a plot plan of off-site property N'-North. This property, bounded by Track Street and South Track Street, occupies approximately 2.6 hectares. An out-of-service railroad track passes through the center of the site. A drainage ditch, portions of which contain debris and building rubble, parallels the track on the north side. The property is presently unused and there are no structures on the site. There are numerous small piles of building rubble, crushed rock and gravel, and miscellaneous metal, rubber, and wood scrap. Light brush and small trees cover the area.

Radiological History

The N'-North area was used during the early 1950's for temporary storage and classification of contaminated scrap from dismantled MED/AEC facilities.¹ Much of this material was removed during the 1950's; however, the 1971-72 AEC survey identified a large portion of the area as having elevated direct radiation levels.² Although additional cleanup was conducted following the AEC survey, areas exceeding 20 $\mu\text{R}/\text{h}$ remained. The 1980 ORNL mobile scan confirmed elevated radiation levels throughout the property bounded by Track Street and South Track Street.

SURVEY PROCEDURES

The comprehensive survey of off-site property N'-North was performed by the Radiological Site Assessment Program of Oak Ridge Associated Universities (ORAU), during September and October 1983. The survey was in accordance with a plan dated March 18, 1983, approved by the Department of Energy's Office of Nuclear Energy. The objective and procedures from that plan are presented in this section.

Objective

The objective of the survey was to provide a comprehensive assessment of the radiological conditions and associated potential health effects, if any, on property N'-North. Radiological information collected included:

1. direct gamma exposure rates and surface beta-gamma dose rates,
2. locations of contaminated surface areas, and
3. concentrations of radionuclides in surface and subsurface soil.

Procedures

1. Brush and weeds were cleared as needed to provide access for gridding and surveying. This operation was performed by Modern Disposal, Inc., of Model City, NY, under subcontract.

2. Under subcontract, McIntosh and McIntosh of Lockport, NY, established a 10 m grid system. This grid is shown on Figure 3.
3. Gamma exposure rate measurements were made at the surface and at 1 m above the surface at 10 m grid intervals. Measurements were performed using portable gamma NaI(Tl) scintillation survey meters. Conversion of these measurements to exposure rates in microroentgens per hour ($\mu\text{R}/\text{h}$) was in accordance with cross calibration with a pressurized ionization chamber.
4. Beta-gamma dose rate measurements were performed 1 cm above the surface at 10 m grid intervals. These measurements were conducted using thin-window ($<7 \text{ mg/cm}^2$) G-M detectors and portable scaler/ratemeters. Measurements were also obtained with the detector shielded to evaluate contributions of nonpenetrating beta and low-energy gamma radiations. Meter readings were converted to dose rates in microrads per hour ($\mu\text{rad}/\text{h}$) based on cross calibration with a thin-window ionization chamber.
5. Surface (0-15 cm) soil samples of approximately 1 kg each were collected at 10 m grid intervals.
6. Walkover surface scans were conducted at 1-2 m intervals over the property. Locations of elevated contact radiation levels were noted.
7. At selected locations of elevated surface radiation levels, beta-gamma dose rates at 1 cm above the surface and exposure rates at 1 m above the surface were also measured. Surface soil samples were obtained from these locations and, following sampling, the surface exposure levels were remeasured to evaluate the effectiveness of shallow sampling on removal of the radiation source.

8. Detection Sciences Group of Carlisle, MA, performed ground-penetrating radar surveys to identify evidence of subsurface targets which might indicate buried waste. Radar scans were also performed at locations of proposed subsurface investigations to identify the presence of underground piping or utilities which would preclude borehole drilling.
9. Boreholes were drilled to provide a mechanism for logging subsurface direct radiation profiles and collecting subsurface soil and water samples. Boreholes were drilled by Site Engineers, Inc., of Cherry Hill, NJ, and Earth Dimensions, of Aurora, NY, using truck mounted 20 cm diameter hollow-stem augers. A total of fifteen boreholes were drilled; the locations of these boreholes are shown on Figure 4.

A gamma scan of the boreholes was performed to identify elevated radiation levels, which would indicate subsurface residues. Radiation profiles in the boreholes were determined by measuring gamma radiation at 15-30 cm intervals between the surface and the hole bottom. A collimated gamma scintillation detector and portable scaler were used for these measurements.

Soil samples of approximately 1 kg each were collected from various depths in the holes by scraping the sides of each borehole with an ORAU designed sampling tool. Water was either not encountered in these boreholes or was present as a result of surface water in the area. There were therefore no subsurface water samples collected.

10. Twenty soil samples and seven water samples were collected from the Lewiston area (but not on the NFSS or associated off-site properties) to provide baseline concentrations of radionuclides for comparison purposes. Direct background radiation levels were measured at locations where baseline soil samples were collected. The locations of the baseline samples and background measurements are shown on Figure 5.

Sample Analysis and Interpretation of Results

Soil samples were analyzed by gamma spectrometry. Radium-226 was the major radionuclide of concern, although spectra were reviewed for U-235, U-238, Cs-137, Th-232, and other gamma emitters.

Additional information concerning analytical equipment and procedures is contained in Appendix A.

Results of this survey were compared to the applicable guidelines for formerly utilized radioactive materials handling sites, which are presented in Appendix B.

RESULTS

Background Levels and Baseline Concentrations

Background exposure rates and baseline radionuclide concentrations in soil, determined for 20 locations (Figure 5) in the vicinity of the NFSS, are presented in Table 1-A. Exposure rates ranged from 6.8 to 8.8 $\mu\text{R/h}$ (typical levels for this area of New York). Concentrations of radionuclides in soil were: Ra-226, <0.09 to 1.22 pCi/g (picocuries per gram); U-235, <0.14 to 0.46 pCi/g; U-238, <2.20 to 6.26 pCi/g; Th-232, 0.32 to 1.18 pCi/g; and Cs-137, <0.02 to 1.05 pCi/g. These concentrations are typical of the radionuclide levels normally encountered in surface soils.

Radioactivity levels in baseline water samples are presented in Table 1-B. The gross alpha and gross beta concentrations ranged from 0.55 to 1.87 pCi/l (picocuries per liter) and <0.63 to 14.3 pCi/l, respectively. These are typical of concentrations normally occurring in surface water.

Direct Radiation Levels

Direct radiation levels, systematically measured at 10 m grid intervals, are presented in Table 2. The gamma exposure rates at 1 m above the surface ranged from 6 to 23 $\mu\text{R}/\text{h}$ (average 11 $\mu\text{R}/\text{h}$). At surface contact, the rates ranged from 6 to 27 $\mu\text{R}/\text{h}$ (average 11 $\mu\text{R}/\text{h}$). Beta-gamma dose rates ranged from 6 to 220 $\mu\text{rad}/\text{h}$ (average 40 $\mu\text{rad}/\text{h}$). Measurements performed with the detector shielded averaged approximately 20% less than those with the unshielded detector. This indicates only a small portion of the surface dose rate is due to nonpenetrating beta or low-energy photon radiations. The highest exposure rates were at grid location 130N, 960E; the highest dose rate was at 120N, 940E. Direct radiation levels were generally higher in the vicinity of the railroad tracks and piles of rock ballast.

The walkover survey identified several small general areas and numerous isolated spots having elevated surface radiation levels. Their locations are indicated on Figure 6 and associated direct radiation levels are presented in Table 3. The maximum contact exposure rate was 520 $\mu\text{R}/\text{h}$ at grid location 28N, 772E. The exposure rate at 1 m above the surface at this location was 16 $\mu\text{R}/\text{h}$ and the surface dose rate was 10,000 $\mu\text{rad}/\text{h}$. The maximum surface dose rate measured was 50,000 $\mu\text{rad}/\text{h}$ at grid coordinate 124N, 953E. Elevated areas of direct radiation were primarily located north of the railroad tracks; many were in or adjacent to the drainage ditch. At a few of the isolated spots, sampling was effective in reducing the radiation levels. In other locations the levels were unchanged or increased as a result of surface sampling.

Radionuclide Concentrations in Surface Soil

Table 4 lists the concentrations of radionuclides measured in surface soil from 10 m grid intervals. These samples contained Ra-226 concentrations ranging from <0.20 to 29.9 pCi/g. Seventy percent of the samples had Ra-226 levels above this baseline range; approximately 13% contained more than 5 pCi/g above the average baseline concentration.

These samples also contained elevated levels of other radionuclides. The highest concentrations were U-238, 125 pCi/g; Cs-137, 4.40 pCi/g; and Th-232, 2.47 pCi/g.

Samples from locations of elevated contact radiation levels contained Ra-226 concentrations ranging from 6.45 to 4290 pCi/g (refer to Table 5). The highest level was obtained at grid location 132N, 950E. Ten of the samples were found to contain small white chips, which were the source of the Ra-226 activity. These chips were evaluated individually and their contents, ranging from 0.13 to 4.21 μ Ci, are presented in Table 6. Some of these samples also contained elevated U-238 levels. For example, B29 had a U-238 concentration of 9430 pCi/g; B28, 1500 pCi/g; B10, 365 pCi/g; and B22, 320 pCi/g. Small yellow chips (possibly yellowcake) were observed in samples B22 and B29. Sample B4 contained 160 pCi/g of Cs-137. Other samples did not contain significant levels of Cs-137 or Th-232.

Ground-Penetrating Radar Findings

The subcontractor's report summarizing ground-penetrating radar survey results for property N'-North is provided in Appendix C. Scans, performed in general areas where elevated surface radiation levels were noted, identified targets at 0.6 to 1.0 m deep. Signals indicate some of these targets are metallic and suggest the presence of shallow buried material scattered throughout the areas.

Borehole Gamma-Logging Measurements

Gamma scintillation measurements performed in boreholes indicated that contamination was limited to the upper 15-30 cm of soil. Gamma-logging data was not used to quantify radionuclide concentrations in the subsurface soil because of the varying ratios of Ra-226, U-235, U-238, Cs-137, and Th-232 occurring in soils from this site.

Radionuclide Concentrations in Subsurface Soil

Table 7 presents the radionuclide concentrations measured in soil samples from boreholes. All of these boreholes were at locations of surface contamination identified by the walkover scan or in the vicinity of subsurface targets indicated by ground-penetrating radar. Although several of the subsurface samples contained radionuclide concentrations slightly above baseline levels, none of the concentrations exceeded guideline levels.

COMPARISON OF SURVEY RESULTS WITH GUIDELINES

The guidelines applicable to cleanup of the off-site properties at NFSS are presented in Appendix B. The maximum exposure rate at 1 m above the ground surface on property N'-North is 27 $\mu\text{R}/\text{h}$ and the average is 11 $\mu\text{R}/\text{h}$. These levels are well below the 60 $\mu\text{R}/\text{h}$ criteria for open land areas.

Areas of surface contamination, identified by the walkover scan, contain Ra-226 concentrations in excess of 5 pCi/g. Several areas contain U-238 levels in excess of 150 pCi/g, and one area has a Cs-137 concentration above 80 pCi/g. Some of these areas are small and isolated and contamination levels would satisfy guideline criteria if averaged over an area of 100 m^2 . There are three larger areas containing multiple regions of contaminated soil and radionuclide concentrations well above the guideline concentrations; averaging over 100 m^2 would not be sufficient to reduce concentrations in these areas to within the appropriate criteria. Locations of areas exceeding guideline levels are summarized in Table 8 and indicated on Figure 7. No subsurface soil samples exceeded cleanup criteria.

SUMMARY

A comprehensive survey of off-site property N'-North at the Niagara Falls Storage Site was conducted during September and October 1983. The survey included surface radiation scans, measurements of direct radiation

levels, ground-penetrating radar scans for buried material, and analyses of radionuclide concentrations in surface and subsurface soil.

The survey identified areas of surface Ra-226 and U-238 contamination exceeding guidelines for unrestricted use. These areas are in the form of small isolated pieces of material and several larger regions of general surface contamination. No subsurface contamination exceeding guideline levels was detected.

Although there are small areas of contaminated residues on portions of this property, the contaminants do not pose potential health risks. There is no evidence of migration of the radioactive materials to adjacent properties.

^a Refer to Table 3 for direct radiation levels.

^b Relatively large errors and poor detection sensitivities are the result of high levels of Ra-226 or U-238 which cause increased continuum count rates.

^c Small sample with high Ra-226 content; activity levels are presented in Table 6.

^d Errors are 2_o based on counting statistics.

APPENDIX A

INSTRUMENTATION AND ANALYTICAL PROCEDURES

APPENDIX A

Instrumentation and Analytical Procedures

Gamma Scintillation Measurement

Walkover surface scans and measurements of gamma exposure rates were performed using Eberline Model PRM-6 portable ratemeters with Victoreen Model 489-55 gamma scintillation probes containing 3.2 cm x 3.8 cm NaI(Tl) scintillation crystals. Count rates were converted to exposure rates ($\mu\text{R}/\text{h}$) using factors determined by comparing the response of the scintillation detector with that of a Reuter Stokes model RSS-111 pressurized ionization chamber at several locations on the NFSS and off-site properties.

Beta-Gamma Dose Rate Measurements

Measurements were performed using Eberline "Rascal," Model PRS-1, portable scaler/ratemeters with Model HP-260 thin-window, pancake G-M, beta probes. Dose rates ($\mu\text{rad}/\text{h}$) were determined by comparison of the response of a Victoreen Model 440 ionization chamber survey meter to that of the G-M probes.

Borehole Logging

Borehole gamma radiation measurements were performed using a Victoreen Model 489-55 gamma scintillation probe, connected to a Ludlum Model 2200 portable scaler. The scintillation probe was shielded by a 1.25 cm thick lead shield with four 2.5 cm x 7 mm holes evenly spaced around the region of the scintillation crystal. The probe was lowered into each hole using a tripod holder with a small winch. Measurements were performed at 15-30 cm intervals in all holes. The logging data were used to identify regions of possible residues and guide the selection of subsurface soil sampling locations. Due to the varying ratios of Ra-226, U-235, U-238, Th-232, and Cs-137, there was no attempt to estimate soil radionuclide concentrations directly from the logging results.

Soil Sample Analysis

Gamma Spectrometry

Soil samples were dried, mixed, and a portion placed in a 0.5 l Marinelli beaker. The quantity placed in each beaker was chosen to reproduce the calibrated counting geometry and ranged from 600 to 800 g of soil. Net soil weights were determined and the samples counted using intrinsic germanium and Ge(Li) detectors coupled to a Nuclear Data Model ND-680 pulse height analyzer system. Background and Compton stripping, peak search, peak identification, and concentration calculations were performed using the computer capabilities inherent in the analyzer system. Energy peaks used for determination of radionuclides of concern were:

Ra-226 - 0.609 MeV from Bi-214 (corrected for equilibrium conditions)

U-235 - 0.143 MeV

U-238 - 0.094 MeV from Th-234 (secular equilibrium assumed)

Th-232 - 0.911 MeV from Ac-228 (secular equilibrium assumed)

Cs-137 - 0.662 MeV

Calibration and Quality Assurance

With the exception of the exposure and dose rate conversion factors for portable survey gamma and beta-gamma meters, all survey and laboratory instruments were calibrated with NBS-traceable standards. The calibration procedures for these portable instruments are described above.

Quality control procedures on all instruments included daily background and check-source measurements to confirm equipment performance was within acceptable statistical fluctuations. The ORAU laboratory participates in the EPA Quality Assurance Program.

APPENDIX B

**SUMMARY OF RADIATION GUIDELINES
APPLICABLE TO OFF-SITE PROPERTIES AT THE NIAGARA FALLS STORAGE SITE**

U. S. DEPARTMENT OF ENERGY

RESIDUAL CONTAMINATION AND WASTE CONTROL CRITERIA
FOR
FORMERLY UTILIZED SITES REMEDIAL ACTION PROGRAM (FUSRAP)
AND
REMOTE SURPLUS FACILITIES MANAGEMENT PROGRAM (SFMP) SITES

Presented here are the residual contamination cleanup and waste control criteria of general applicability to the FUSRAP project and remote SFMP sites^{1/}.

With the exception of limits for radium-226, the soil residual contamination criteria were developed on the basis of limiting maximum individual radiation exposure to DOE limits specified in DOE Order 5480.1A exclusive of exposure from natural background radiation or medical procedures. The aggregate of the contribution from all major pathways, based on scenarios for permanent intrusion, e.g., establishing residences on the site, has been assumed. In most circumstances, the probability is low that such an intrusion will occur. Also, conservative assumptions were used in deriving these criteria to ensure that a particular dose limit would not be exceeded. Use of these criteria is additionally conservative because the pathways considered in the derivation of the criteria assume all water intake and most food intake is from the site. Also, the sites often have limited agricultural capability and the contamination is generally not homogeneous. The combined effect of these factors is such that the probable radiation exposure to the average population on, or in the vicinity of, FUSRAP sites decontaminated to these criteria limits will not be appreciably different from that normally received from natural background radiation.

The residual contamination criteria for surface contamination of structures were developed from a proposed ANSI standard^{2/} modified as appropriate to be consistent with DOE Order 5480.1A and the specific needs of FUSRAP for cost-effective, workable guidelines which provide an adequate safety margin. The waste control criteria are consistent with applicable DOE Orders and EPA's regulations for inactive uranium milling sites, 40 CFR 192.

^{1/}A remote SFMP site is one that is excess to DOE programmatic needs and is located outside a major operating DOE R&D or production area. Remote sites are more likely to be released to the public or excessed to other government agencies after decontamination than are sites located with major R&D or production areas.

^{2/}ANSI N13.12 (proposed) -- an adaptation to be applied, as appropriate.

A. RESIDUAL CONTAMINATION CRITERIA FOR FORMERLY UTILIZED SITES AND REMOTE SURPLUS FACILITIES MANAGEMENT PROGRAM SITES

The following criteria represent the maximum residual contamination limits for unrestricted use of land and structures contaminated with radionuclides related to the nuclear fuel cycle at FUSRAP and remote SFMP sites. It is the policy of DOE to decontaminate sites to contamination levels at or below the limits and in a manner consistent with DOE's as-low-as-is-reasonably-achievable (ALARA) policy. Residual contamination limits for other nuclides will be developed when required using the same methodology as was used for those represented here.

1. Soil (Land) Criteria (Maximum Limits for Unrestricted Use)

Soil Criteria^{2/,3/,4/}
(pCi/g above background)

Radionuclide

U-Natural^{5/}

75

U-238^{6/}

150

U-234^{6/}

150

Th-230^{7/}

15

Ra-226

5 pCi/g, averaged over the first 15 cm of soil below the surface; 15 pCi/g when averaged over 15 cm thick soil layers more than 15 cm below the surface and less than 1.5m below the surface.

U-235^{6/}

140

Pa-231

40

Ac-227

190

Th-232

15

Am-241^{8/}

Sr-90

100

H-3 (pCi/ml soil moisture)

5,200

1/ Described in ORO-831 and ORO-832.

2/ In the event of occurrence of mixtures of radionuclides, the fraction contributed by each radionuclide to its limit shall be determined, and the sum of these fractions shall not exceed 1. There are two special cases for which this rule must be modified:

- (a) If Ra-226 is present, then the fraction for Ra-226 should not be included in the sum if the Ra-226 concentration is less than or equal to the Th-230 concentration. If the Ra-226 concentration exceeds the Th-230 concentration, then the sum shall be evaluated by replacing the Ra-226 concentration by the difference between the Ra-226 and Th-230 concentrations.
- (b) If Ac-227 is present, then the same rule given in (a) for Ra-226 relative to Th-230 applies for Ac-227 relative to Pa-231.

3/ Except for Ra-226, these criteria represent unrestricted-use residual concentrations above background averaged across any 15 cm thick layer to any depth and over any contiguous 100 m² surface area. The same conditions prevail for Ra-226 except for soil layers beneath 1.5 m; beneath 1.5 m, the allowable Ra-226 concentration may be affected by site-specific conditions and must be evaluated accordingly.

4/ Localized concentrations in excess of these limits are allowable provided that the average over 100 m² is not exceeded.

5/ A curie of natural uranium means the sum of 3.7×10^{10} disintegrations per second (dis/s) from U-238 plus 3.7×10^{10} dis/s from U-234 plus 1.7×10^5 dis/s from U-235. One curie of natural uranium is equivalent to 3,000 kilograms or 6,600 pounds of natural uranium.

6/ Assumes no other uranium isotopes are present.

7/ The Th-230 guideline is 15 pCi/g to account for ingrowth of Ra-226 as Th-230 decays. Ra-226 is a limiting radionuclide because its decay product is Rn-222 gas.

8/ The Pu-241 criterion was derived from the Am-241 concentration.

2. Structure Criteria (Maximum Limits for Unrestricted Use)

a. Indoor Radon Decay Products

A structure located on private property and intended for unrestricted use shall be subject to remedial action as necessary to ensure the annual average concentration of radon decay products is less than 0.03 WL within the structure.

b. Indoor Gamma Radiation

The indoor gamma radiation after decontamination shall not exceed 20 microroentgen per hour ($20 \mu\text{R}/\text{h}$) above background.

c. Indoor/Outdoor Structure Surface Contamination

<u>Radionuclides</u>	<u>Allowable Surface Residual Contamination^{1/} (dpm/100 cm²)</u>	<u>Total</u>	<u>Removable</u>
<u>Group 1:</u>		100	20
Radionuclides for which the uncontrolled area concentration guide in air above background is 2×10^{-13} Ci/m ³ or less or for which the uncontrolled area concentration guide in water above background is 2×10^{-29} Ci/m ³ or less; includes Pa-231, Th-228, Th-230, Ac-227, Ra-226, Ra-228, and Pb-210.			
<u>Group 2:</u>		1,000	200
Radionuclides not in Group 1 for which the uncontrolled area concentration guide in air above background is 1×10^{-12} Ci/m ³ or less or for which the uncontrolled area concentration guide in water above background is 1×10^{-6} Ci/m ³ or less; includes U-232, U-238, Th-232, Ra-223, and Po-210.			
<u>Group 3:</u>		5,000	1,000
Those radionuclides not in Group 1 or Group 2; includes U-234, U-235, and Ra-224 and all other beta-gamma emitters.			

^{1/}The levels may be averaged over 1 m² provided the maximum activity in any area of 100 cm² is less than 3 times the limit value; dpm = disintegrations per minute. In the event of occurrence of mixtures of radionuclides, the fraction contributed by each radionuclide to its limit shall be determined, and the sum of these fractions shall not exceed 1.

^{2/}Given in Attachment 1 to Chapter XI, Table II, DOE Order 5480.1A.

B. CONTROL OF RADIOACTIVE WASTES AND RESIDUES FROM FUSRAP AND REMOTE SFMP SITES

Specified here are the control requirements (criteria) for radioactive wastes and residues related to the nuclear fuel cycle at FUSRAP and remote SFMP sites.

1. Interim Storage

All operational and control requirements specified in the following DOE Orders shall apply:

- a. 5480.1A, Environmental Protection, Safety, and Health Protection Program for DOE Operations.
- b. 5480.2, Hazardous and Radioactive Mixed Waste Management.
- c. 5483.1, Occupational Safety and Health Program for Government-Owned Contractor-Operated Facilities.
- d. 5484.1, Environmental Protection, Safety, and Health Protection Information Reporting Requirements.
- e. 5484.2, Unusual Occurrence Reporting System.
- f. Control and stabilization features will be designed to ensure, to the extent reasonably achievable, an effective life of 50 years, and in any case, at least 25 years.
- g. Rn-222 concentrations in the atmosphere above facility surfaces or openings shall not (1) exceed 100 pCi/l at any given point, or an average concentration of 30 pCi/l for the facility site, or (2) exceed an average Rn-222 concentration at or above any location outside the facility site of 3.0 pCi/l (above background).
- h. For water protection, use existing state and federal standards; apply site-specific measures where needed.

2. Long-Term Management

- a. All operational requirements specified for Interim Storage Facilities (B.1) will apply.
- b. Control and stabilization features will be designed to ensure to the extent reasonably achievable, an effective life of 1,000 years and, in any case, at least 200 years. Other disposal site design features shall conform with 40 CFR Part 192 performance guidelines/requirements.

- c. Rn-222 emanation to the atmosphere from facility surfaces or opening shall not (1) exceed an average release rate of 20 pCi/m²/s, or (2) increase the annual average Rn-222 concentration at or above any location outside the facility site by more than 0.5 pCi/l.
- d. For water protection, use existing state and federal standards; apply site-specific measures where needed.
- e. Prior to placement of any potentially biodegradable contaminated wastes in a Long-Term Management Facility, such wastes will be properly conditioned to (1) ensure that the generation and escape of biogenic gases will not cause the criteria in paragraph 2.c. to be exceeded, and (2) ensure that biodegradation within the facility will not result in premature structural failure not in accordance with the criteria in paragraph 2.b.. If biodegradable wastes are conditioned by incineration, incineration operations will be carried out in compliance with all applicable federal, state, and local air emission standards and requirements, including any standards for radionuclides established pursuant to 40 CFR Part 61, National Emission Standards for Hazardous Air Pollutants (NESHAPS).

C. EXCEPTIONS

- 1. Procedure -- Analysis of site-specific conditions.
- 2. Applicability -- Where health and safety would be endangered, or where cost clearly outweighs benefits.

D. CRITERIA SOURCE

<u>Criteria</u>	<u>Source</u>
<u>Residual Contamination Criteria</u>	^{1/} DOE Order 5480.1A, 40 CFR Part 192 ^{2/}
Soil Criteria	
<u>Structure Criteria</u>

DETECTION SCIENCES GROUP

INTRODUCTION AND SUMMARY

On October 11-14 and October 17, 1983, Detection Sciences Group performed a ground-penetrating radar survey of Property N-N' North at the former Lake Ontario Ordnance Works, Lewiston, New York. The survey was performed in accordance with Oak Ridge Associated Universities, Inc. Purchase Order No. C-29932-008, Letter Release No. 8, dated October 11, 1983. The survey work was conducted under the field direction and instructions of O.R.A.U. personnel.

On October 11 and 12, four grid-surveys were made in Area N-N' North. The first area to be surveyed ran from 10N to 72N, covering 5 meter intervals from 770E to 810E. The results of this grid survey are listed in Table I, and are illustrated in Figure 1.

The second area to be surveyed ran from 74N to 126N, covering 5 meter intervals from 870E to 890E. The results of this grid survey are listed in Table II, and are illustrated in Figure 2.

The third area to be surveyed ran from 105N to 154N, covering 5 meter intervals from 920E to 960E. The results of this grid survey are listed in Table III, and are illustrated in Figure 3.

The fourth area to be surveyed ran from 153N to 190N, covering 5 meter intervals from 1000E to 1020E. The results of this grid survey are listed in Table IV, and are illustrated in Figure 4.

With the exception of Figure 4, it will be noted that the radar anomalies tend to be clustered along an orientation that is parallel to the railroad tracks, and parallel to the associated access roads along the tracks. This is particularly evident in Figures 1 and 2. This radar evidence indicates that the former use of the site was closely linked to the existence of the railroad.

On October 13, 14 and 17, 1983, a total of 11 systematic borings were inspected on Property N-N' North. (This procedure has been described in detail in the Final Report on Property G, dated August, 1983, and will not be iterated here.) Potential drilling obstacles were found at 2 of the 11 locations. The proposed locations for the 11 borings and the final locations of the borings are listed in Table V.

The designations of the borings, N1 through N11 for the systematic borings, are designations assigned by Detection Sciences Group in accordance with the sequence in which the borings were inspected, and are not designations assigned by O.R.A.U.

A separate binding, titled "Radar Graphic Charts, Area N-N' North, Systematic Borings", contains all of the radar charts of borings inspected in Area N-N' North. The proposed location for the boring is the centerpoint of each chart, shown by a pair of vertical dashed lines. The final location of each boring is shown by the arrow at the top of each chart. The vertical scale for all of the boring inspection charts is 1 inch = 1 foot. A separate binding titled "Radar Graphic Charts, Area N-N' North, Grid Surveys" shows the vertical profiles and the anomalies along each grid line. The vertical scale of these charts is 1" = 2 feet.
